

Paper title over at most two lines

Subtitle: method or angle in one line

Author One ▪ Author Two ▪ Author Three*

Affiliation One ▪ Affiliation Two

CONF 2026 ▪ Month Day–Day, 2026 ▪ City, Country

Outline

01 Introduction One-line description of part one.

02 Model One-line description of part two.

03 System One-line description of part three.

04 Results One-line description of part four.

01

Introduction

One sentence on why this problem matters and where the bottleneck lies.

Plain bullets frame: state the frame title as a claim

- One point = one message: state the fact first, then its consequence.
- Quantify where possible; numbers beat adjectives in review rooms.
- Use **accent** only on the two or three words that carry the argument.
- Close the frame with the takeaway, not with a detail.

Key insight: one sentence the audience must remember from this frame — stated, not hinted.

Three-card frame: three parallel streams or contributions

1 First card

Two to four lines describing stream one.

2 Second card

Two to four lines describing stream two.

3 Third card

Two to four lines describing stream three.

Shared limitation: the one sentence that motivates your work, following the three cards.

Vertical list frame: long texts read better in full-width rows

1 First item headline Grey sub-note in one line.

2 Second item headline Grey sub-note in one line.

3 Third item headline Grey sub-note in one line.

Figure frame: text left, figure right

Paper figure placeholder
replace with `\includegraphics`

Group head short setup sentence.

- Dense annotations go here in scriptsize.
- **Highlight** the one arc/rule that matters most.

Second group head more structure.

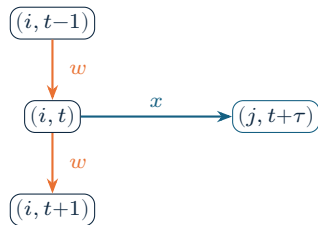

Goal: one-line objective or takeaway card

Diagram frame: text left, schematic right

Explain the mechanism in prose; bold the arc names in **accent**:

- **Flow one** $(i, t) \rightarrow (j, t+\tau)$ — what it carries.
- **Flow two** — what it carries.
- **Flow three** — what it carries.

⇒ the one-line conclusion of the mechanism.

■ flow two ■ flow one

Table frame: table left, reading right

Table head

Type	a	b	c
Row one	1	2	0.25
Row two	2	4	0.5
Row three	3	6	1

One-line caption; note the highlighted entries.

Assumptions / reading

1. First assumption, stated so a reviewer can attack it.
2. Second assumption; name what it buys you.
3. Third assumption and its boundary.

Mathematical model (1/2): objective & conservation

Objective — charge each flow with its unit cost and footprint:

$$\min \sum_{t, (i,j) \in \mathcal{A}} \sum_g c_{ij}^f \theta_g x_{ijg}^t + \sum_{t, i, g} c_i^h \theta_g w_{ig}^t + \sum_{t, i, g} c_i^r \theta_g r_{ig}^t$$

Flow conservation at every vertex, one line per node class:

$$\begin{aligned} w_{ig}^{t-1} + S_{ig}^t + r_{ig}^t &= y_{ig}^t + w_{ig}^t + \sum_{\mathcal{A}_i^+} x^t && \text{depots } i \in D \\ S_{pg}^t &= \sum_{\mathcal{A}_p^+} x^t && \text{sources } p \in P \\ \sum_{\mathcal{A}_q^-} x^t &= y_{qg}^t && \text{sinks } q \in Q \end{aligned}$$

Notation: x flow · w inventory · r rent · S supply · y service · θ_g footprint · $\mathcal{A}_i^\pm$ out-/in-arcs of i

Mathematical model (2/2): couplings & boundary conditions

[COUPLING A] What binds the types together — one sentence on its role:

$$\sum_g x_{ijg}^t = D_i^t \quad \forall i, t$$

[COUPLING B] Shared capacity — one budget across all types:

$$\sum_g \theta_g x_{ijg}^t \leq F_{ij}^{\max} \quad (\text{arc}) \qquad \sum_g \theta_g w_{ig}^t \leq U_i^{\max} \quad (\text{node})$$

[BOUNDARY] Terminal condition — rule out end-of-horizon artifacts:

$$w_{ig}^T \geq \bar{I}_{ig} \quad (\text{set } \bar{I}_{ig} = I_{ig}^0 \Rightarrow \text{no-net-depletion})$$

Integrality: $x_{ijg}^t, w_{ig}^t, r_{ig}^t, y_{ig}^t \in \mathbb{Z}_+$ — units are discrete; initial state $w_{ig}^0 = I_{ig}^0$ fixed.

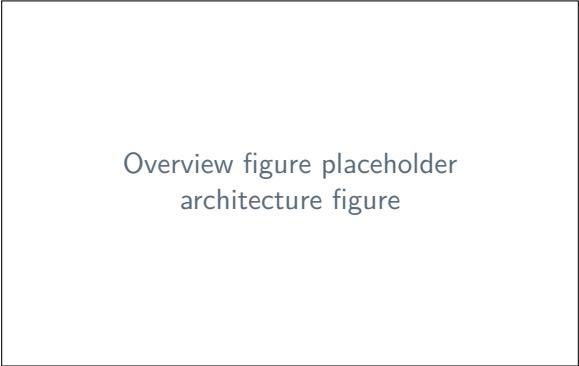

One sentence on why this model is genuinely the coupled one — remove the named couplings and it splits apart.

Overview frame: pinned panel + figure

Panel headline

Two to five lines positioning the figure:
what is grounded by what, and what
makes it robust.

*The italic kicker line that states the
design philosophy.*

Overview figure placeholder
architecture figure

Routing-table frame: symptom, stage, action

One framing sentence above the table:

Symptom	Where	Action
symptom one	stage one	action one
symptom two	stage two	action two
symptom three	stage three	action three

Complementary by design: one closing sentence that pairs the two mechanisms on this frame.

Result 1 — headline number with evidence

1,234,567.8

the claim in three words

qualifier (gap $< 10^{-6}$, MIPGap= 0)

Why the number is trustworthy:

- Identical size: 1317×2740 , 7556 nonzeros
- Identical structure after presolve
- Differences only in iteration counts — a code-level artifact
- Same final plan / decision vector

⇒ One-sentence takeaway.

Result 2 — scenario comparison

Scenario bar-chart placeholder

Axis label and unit, one line

Scenario	Total	Δ
S1 Baseline	1,234,567	—
S2 No channel A	1,320,000	+7.0 %
S3 No channel B	1,490,000	+20.7 %

+27.9 % total cost if both channels
are disabled

Which channel dominates, in one line.

Composition & insights

Where the budget goes

- Component one 62 % — driven by what
- Component two 19.5 % — residual role
- Component three 18 %
- Component four < 1 %

What varies across scenarios

Only the dominant component responds — so the lever's value lands where the cost is.

Where to prioritize

Name the dominant lever and its share (50 %).

Give the per-unit saving numbers.

⇒ *Managerial message: with modeling automated, planner attention is best spent framing the scenario, not hand-crafting the model.*

Conclusion & future work

What we did

- The system in one line: input → output.
- Its three parts, in three short bullets.
- Validation result on the real case.
- The operational finding, with its number.

Positioning

Where this sits in the field, in two lines.

Future work

Direction one; direction two; direction three.

Thank you!
